(54) Title: LOCAL MULTIPONT DISTRIBUTION SERVICE BASE STATION APPARATUS

(57) Abstract

A local multipoint distribution service base station apparatus for sending and receiving communication signals to and from subscribers includes a base unit having at least one rack which is adapted to receive at least one subrack. At least one communication signal generating unit is also arranged and configured to be received by the subrack. In addition, a transmitting/receiving unit is operationally connected to the base unit for transmitting and/or receiving the communication signals to and from the subscribers.

LOCAL MULTIPONT DISTRIBUTION SERVICE BASE STATION  
APPARATUS

TECHNICAL FIELD OF THE INVENTION

The present invention generally relates to a local multipoint distribution service (LMDS) system or local multipoint communication system (LMCS), and more 5 particularly to the base station architecture of the LMDS system.

BACKGROUND OF THE INVENTION

The LMDS system provides a "wireless local loop" or 10 the "last mile" link to subscribers for fixed communication services such as video and telephony including data information such as facsimile and computer signals. The LMDS system includes a base station or node for sending and receiving selected communication signals to and from a customer premises equipment (CPE) which is remotely located 15 with the subscribers. In addition to the CPE, the base station is also connected to a video serving office or other distribution centers for video content and to a central office switched telephony network for telephony 20 services. A typical LMDS system consists of several base stations per central office and video serving office, and several thousand CPE sites per base station. In this manner, the LMDS system is a "point-to-multipoint" cellular communication system, the base station being the point, and 25 the CPE sites, the multipoint. The connection between the

base station and the subscribers is generally through broadband radio frequency (RF). The bandwidth depends on the spectrum allocation but is generally about 1 GHz. The subscriber equipment or CPE tunes to one or more RF frequency channels within the 1 GHz band to connect to the 5 base station.

It is cost effective to have the capacity of the base station correspond to the demand of the subscribers linked to the base station at a given time. However, it is 10 difficult to predict the number of subscribers who will be linked to the base station, especially when the LMDS system is initially being implemented. Consequently, if the number 15 of subscribers grows unexpectedly from the initially projected number, a conventional base station would not be capable of servicing all the subscribers without an extensive and time consuming reconfiguration of the base station, which is an expensive operation. On the other hand, if the number of subscribers predicted is too high or 20 if a significant number of the subscriptions is canceled, the base station would operate at undercapacity.

Also, the conventional base stations generally include a base unit and a remote unit which are physically partitioned from each other. The remote unit includes an antenna which is located, for example, on a tower or on top 25 of a building, and is connected to the other parts of the remote unit via a long wave-guide. A disadvantage of using a long waveguide is that it is expensive and prone to excessive loss (approximately 15 dB/100ft). Routing the wave-guide to the top of a building, for example, is also 30 a difficult task.

SUMMARY OF THE INVENTION

In accordance with the present invention, an approved base station for cost effectively implementing an LMDS system is provided.

5 In one embodiment of the present invention, a local multipoint distribution service base station apparatus is disclosed for sending and receiving communication signals to and from a plurality of remotely located subscriber equipment. The apparatus includes a base station having at least one rack, the rack configured and adapted to receive at least one sub-rack. The apparatus also includes at least one communication signal generating means arranged and configured to be received by at least one sub-rack. Also, a transmitting/receiving unit is operationally connected to the base unit for transmitting and receiving the communication signals to and from the subscriber equipment.

20 Technical advantages of the present invention include an improved base station having a base unit which has a modular configuration to allow operation of both small and large systems. The base station may also adopt a modular configuration for grouping similar functions in approximately located shelves to minimize cabling and RS signal impairments. The base unit may also include a 25 remote unit which minimizes the length of the waveguide between an antenna and the other remote unit electronics. In a particular embodiment, this remove unit integrates an antenna in the associated transmitter and receiver into a single assembly.

30 Other technical advantages are readily apparent to one skilled in the art from the following figures, descriptions, and claims.

BRIEF DESCRIPTION OF THE DRAWINGS

For a more complete understanding of the present invention, and for further features and advantages, reference is now made to the following description, taken in conjunction with the accompanying drawings, in which:

FIGURE 1 is a block diagram of a local multipoint distribution service system of this invention;

FIG. 2 is a block diagram of a base station embodying the present invention;

FIG. 3 is a front view of the base unit of FIG. 2;

FIG. 4 is a front view one of the racks of FIG. 3;

FIG. 5 is a perspective view of one of the racks of FIG. 3;

FIG. 6 is a front view of one of the racks of FIG. 3;

FIG. 7 is a side view of the rack of FIG. 6;

FIG. 8 is a perspective view of a rack enclosed in a housing;

FIG. 9 is a perspective view of a remote unit embodying the present invention; and

FIG. 10 is a side view of the remote unit of FIG. 9, with the cover removed.

DETAILED DESCRIPTION OF THE INVENTION

The present invention is directed to the architecture of a base station of a local multipoint distribution cellular communication system that can provide telephony/data and video services to residential, business and educational facilities. One of the novel features of the present base station is that the components of the base station are provided in modules according to their functions, so that these modules can be added or removed correspondingly with an increase or a decrease in demand on the base station. Another novel feature of the present invention is that the antenna is integrated into an assembly with the electronics of the transmitting/receiving unit of the base station.

Broadly stated, a local multipoint distribution service base station apparatus for sending and receiving communication signals to and from a plurality of remotely located subscriber equipment includes a base unit having, at least one rack which is configured and adapted to receive at least one subrack. Also, at least one communication signal generating unit is arranged and configured to be received in the subrack. A transmitting/receiving unit is operationally connected to the base unit for transmitting and receiving the communication signals to and from the subscriber equipment.

In another embodiment, a local multipoint distribution service base station apparatus for sending and receiving communication signals to and from subscriber equipment includes a communication signal generating unit for generating the communication signals. A transmitting/receiving unit is operationally connected to the communication signal generating unit and is adapted to transmit/receive the communication signals to and from the

subscriber equipment. Also, an antenna unit is operatively connected to the transmitting/receiving unit for directing and receiving the communication signals to and from the subscriber equipment. The antenna unit and the transmitting/receiving unit are arranged and configured into an integrated assembly.

Turning now to the drawings, and particularly FIG. 1, a block diagram of a local multipoint distribution service (LMDS) system, indicated generally at 20, is shown and generally includes a base station or node 22 having a base unit 24 and a remote unit 26. The remote unit 26 is linked to a customer premises equipment (CPE) 28 which receives video, and/or telephony services from the base station 22. The base unit 24 is connected to a video serving office (VO) 30 or other distribution centers that provide the video content to the base station 22. Also connected to the base unit 24 is a central office (CO) switch 32 which provides the telephony services.

Turning now to FIG. 2, the base unit 24 includes a multiplexer 34 which connects the base station 22 to the VO 30 and the CO 32 via a known "backhaul" network 35 such as a NOC-x synchronous optical network (SONET) ring or a DS3 network, which are broad bandwidth networks. If the connection is made to a DS3 network, the multiplexer 34 provides the multiplexing from DS3 (44 Mbps) rates to DS1 (1.544 Mbps) rates and if connected to a SONET network, the multiplexer 34 translates from OC-48 (2.488Mbps) rates to OC-3 (155 Mbps) rates.

The video signals from the multiplexer 34 are supplied to the video unit 36 which allows the mapping between RF channels, in which the video signals are sent to the subscribers, and the backhaul channels. The RF carriers containing the video channels can be analog or digitally

modulated. The telephony signals from the multiplexer 34 are supplied to a telephony unit 38 which performs multiplexing and demultiplexing functions to convert downstream signals (base station to CPE) and upstream signals (CPE to base station) into asymmetric data streams.

5 For downstream transmission, the telephony unit bundles as much traffic as possible into a downstream RF carrier. For example, the industry standard transmission format such as OC-3, DS1 or E1 (2.048 Mbps) is bundled into a high-speed time-division-multiplexed signal (e.g., DS3). In the preferred embodiment, the bundled signal contains 28 Tls, (44.7 Mbps) or 16 Els for international applications. Additional control bytes are added for forward error correction, radio control, and potentially for encryption.

10

15 Thus described feature in which data is sent at an asymmetric rate during the upstream and downstream transmissions is an important aspect of the present invention. High-speed telephony downstream transmission is ideally suited for a point-to-multipoint communication in that the signals are broadcast to all receivers. Each receiver tunes to a designated frequency and time slot; however, each receiver has access to any downstream signals. The receiver demultiplexes the downstream signals to recover only the bit stream of interest. By increasing 20 the downstream data rate, the number of downstream transmitters (or number of RF carriers per transmitter) can be reduced. In addition, every RF channel requires some amount of guard-band to prevent adjacent channel interference. Fewer channels take fewer guard-bands and therefore, more payload can be sent per a given band. As a 25 result the spectral efficiency is increased.

30

Upstream transmission is performed at a lower rate of about 3.3 Mbps which accommodates both DS1 and E1 payloads

and can be either in continuous format or burst format. The telephony unit 38 is used to reformat the data to a symmetric format for transmission by the multiplexer 34 to the backhaul network 35. Continuous format supports fixed services such as T1 or E1. In burst mode, multiple CPEs 28 can share an RF channel using a time-division multiple access (TDMA) scheme. With the TDMA scheme, the time of transmission of a burst must be timed such that the bursts arrive at the receiving base station 22 at a precise time. Preferably, the burst format consists of a 28 byte packet in a 2 milli-second frame to support the DS1 telephony frame rate. In this manner, twenty-four subscribers can be accommodated on a single RF channel which provides full rate 64 kbps service to each CPE 28.

Modulators 40 (one shown), which are digital video broadcast (DVB) compliant, for example, connect to the output of the video unit 36 and the telephony unit 38, and modulate the received signals onto a L-band, intermediate frequency signals (950 to 1950 MHZ), and send the modulated signals to the remote unit 26. The digital video and the telephony signals are preferably quadrature phase shift key (QPSK) modulated, which requires less signal-to-noise ratio than most other modulation formats, and therefore provides the longest range. For analog video signals, the invention can be implemented such that the modulators 40 perform frequency modulation (FM). Upstream signals received from the CPE 28 via the remote unit 26 are supplied to demodulators 42 (one shown) which perform a QPSK demodulation and send the signals onto the telephony unit 38.

Another important aspect of the present invention is that a master oscillator 44 provides a single frequency reference which is tracked by all the frequency setting

components in the LMDS system 20. Throughout the base unit 24, oscillator signals are frequency division multiplexed onto combiner and distributed networks (not shown) along 6 with payload signals to minimize the need for a separate 5 network to distribute the oscillator signals. In the preferred embodiment an optional pilot tone generator 46 which is a special oscillator that is frequency locked to the master oscillator 44 is used to lock the oscillators on the remote unit 26 and the CPE 28. It can be located either 10 in the base unit 24 as in the preferred embodiment, or in the remote unit 26 and operates at about 960 MHZ for example. Alternatively, two optional pilot tone generators 46 and two master oscillators 44 can be employed in the base station 22 for redundant implementation.

15 A node controller 48 contains a database of all the provisional items (objects) at the base station 22 and the CPE 28, and provides overall control, provisioning and alarm processing functions. A power system 50 is also provided for converting in-country prime power to -48VDC 20 which is distributed through the base and the remote units 24, 26.

The base unit 24 is connected to the remote unit 26 via a fiber optic link 52 which carries the signals transmitted between the two units 24, 26. The fiber optic 25 link 52 is preferable because it provides better immunity to lighting than copper wires, and allows the remote unit 26 to be located from the base unit 24 by as long as several miles. For example, the remote unit 26 may be placed on a tower or a tall structure such as a building, 30 and the base unit 24 may be located in an equipment room or remotely from the remote unit 26 in an equipment building such as the central office 32. It should be noted that a coaxial cable(s) may also be employed to connect the base

10.

unit 24 and the remote unit 26 instead of the fiber optic link 52.

An intermediate frequency (IF) protocol is used to interface the base unit 24 with the remote unit 26 to allow the base unit to be independent of the operating frequency of the remote unit. In this manner, different tower equipment assemblies can be "plugged" into a common base unit 24 to solve the problem of supporting different RF bands. L-band IF is preferred because it is high enough so that frequency conversion to 28 GHz can be accomplished in one translation stage and is low enough such that RF components are readily available and reasonably inexpensive. It is contemplated that wireless point-to-point radio can also be used as the connection between the base unit 24 and the remote unit 26.

The remote unit 26 includes a transmitter/up-converter 54 which is connected to the modulator 40 via the fiber optic link 52 for converting the IF signals from the modulator to RF carrier signals, and sending the converted RF signals to the CPE 28. A receiver/down-converter 56 receives the RF signals from the CPE 28 and converts the RF signals to the IF signals, which is then sent to the demodulator 42 in the base unit 22 via the fiber optic link 52.

Distributed oscillators 58 are included to act as separate milli-meter local oscillators for providing reference signals to each of the transmitter/up-converter 54 and the receiver/down-converter 56 for up and down frequency conversions. The oscillators 58 are connected via the fiber optic link 52 to the optional pilot tone generator 46 which provides the preferred common reference frequency of 960 MHZ. By having a separate oscillator 58 for each of the transmitter/up-converter 54 and the

5 receiver/down-converter 56, a problem of having to have a milli-meter wave distribution network is avoided. The distribution network reduces flexibility because it requires knowing the number of ports and mechanical arrangement of the transmitter/up-converter and the receiver/downer-converter 54, 56.

In the preferred embodiment, a remote unit controller 60 is operatively connected to the node controller 48 of the base unit 24 via the fiber optic link 52 and acts as a 10 central control computer that collects alarm information and provides a collection point of the control and communications away from the remote site. It should be noted that the utilization of the remote unit controller 60 in the present invention is optional, and that the 15 functions of the remote unit controller can be performed by the node controller 48. The remote power supply 62 is connected to the power system 50 of the base unit 24 and provides the preferred -48VDC power needed for transmitting and receiving signals to and from the CPE 28.

20 It is important to note that the base unit 24 may include multiple numbers of each of the components described above depending on the number of subscribers the base unit is designed to service. Thus, one important feature of the present invention is that the components of 25 the base unit 24 performing the same function are physically grouped together into individual modules. Such modular configuration is shown in FIG. 3 in which the base unit 24 is arranged into a number of subracks or shelves 64 within five racks 66. While the base unit 24 shown in FIG. 30 3 includes one video unit 36 and three telephony units 38, this is only intended to be an example. The actual number of each of the base unit 24 components is dictated by the subscriber capacity, i.e., subracks 64 and racks 66 can be

added to increase capacity and removed to decrease capacity. Increasing and decreasing capacity would only require connecting or disconnecting one or more racks 66 to and from the base station 22. In this manner, the modular configuration of the present invention allows the LMDS system 20 to easily adapt to the needs of the subscribers.

In the preferred embodiment, each of the racks 66 includes one subrack 64 for housing the node controller 48. The network of these node controllers 48 in the base unit 24 provides control of equipment settings such as transmission levels, power up sequencing, fault detection and switching, performing monitoring and remote control from a central network management facility. Communication between the racks 66 is preferably through ethernet, and communication between subracks 64 is preferably through an RS-485 bus for low data rate subracks and a VME bus for high data rate subracks. It is important to note that in the preferred embodiment, the subracks 64 having similar functions are arranged so that they are in close proximity to each other. For example, the node controllers 48 are adjacent each other, the telephony units 38 are also adjacent each other and so are the demodulators 42. This is to minimize cabling and RF signal impairments.

Turning now to FIG. 4, each of the components in the base unit 24 are integrated onto at least one circuit card assembly (CCA) 68, which are adapted to be received by the subracks 64. The CCAs 68 plug into the subracks 64 and are designated as "line replaceable items" which allow for "live insertion" or "hot swap". Preferably, the connection or "make" of the CCA 68 to the subrack 64 at a connector terminal (not shown) is made in tile order of ground power and signal and the disconnection or "break" is made in the order of signal, power and ground. The dimensions of the

subracks 64 specifically the height and the depth, vary accordingly to accommodate the size of the CCAs 68. However, the width should be such that the CCAs 68 is able to fit horizontally between a pair vertical sections 70 (best seen in FIG. 5) of the racks 66. The modularity of the CCA 68 allows components of the base unit 24 to be added or removed with capacity, and repairs to be made by merely replacing the faulty CCA.

Turning now to FIGS. 6 and 7, one of the racks 66 in FIG. 3 is shown independently, and preferably has a width, as indicated by an arrow 72, of approximately 20 inches, a height, as indicated by an arrow 74, of approximately 84 inches and a depth, as indicated by an arrow 76, of approximately 6 inches. It should be noted that the size of the racks 66 may be varied as necessary to desired dimensions.

Turning to FIG. 8, the racks 66 and their subracks 64 are preferably fully encased in a housing 78 having an access door 80 in order to meet the conducted and radiated emissions requirement. An open frame racks 66 may also be utilized, provided that the individual CCAs 68 within the subracks 64 are adequately shielded.

Turning now to FIGS. 9 and 10, the remote unit 26 is shown to include a radome/polarizer 82, an antenna 84 and an electronic housing 86. An important feature of the present invention is that these components are integrated into a single assembly, with a wave-guide 88 (best shown in FIG. 10, which is a side view the remote unit with cover of the housing 86 removed) connecting the antenna 84 with the components within the electronic housing 86. This arrangement significantly reduces the length of the wave-guide 88, so that the signal loss inherently associated with the wave-guide is minimized.

From the foregoing detailed description, it should be understood that a LMDS base station apparatus for sending and receiving telephony and video signals to and from multitude of subscribers has been shown which has many advantages and desirable attributes. Of particular advantage is the ability to add capacity in a modular fashion by organizing the various functions of the base station into subracks or shelves. Another advantage is that the antenna and the associated electronics are integrated into a single housing thereby reducing the length of the connection between the antenna and the other components.

While various embodiments of the present invention have been shown and described, it should be understood that other modifications, substitutions and alternatives are apparent to one of ordinary skill in the art. Such modifications, substitutions and alternatives can be made without departing from the spirit and scope of the invention, which should be determined from the appended claims.

Various features of the invention are set forth in the appended claims.

WHAT IS CLAIMED IS:

1. Local multipoint distribution service base station apparatus for sending and receiving communication signals to and from a plurality of remotely located subscriber equipment, comprising:  
5

a base unit including at least one rack, said rack configured and adapted to receive at least one subrack;

10 at least one communication signal generating means arranged and configured to be received by said at least one subrack;

a transmitting/receiving unit operationally connected to said base unit for transmitting and receiving the communication signals to and from the subscriber equipment.

15 2. A base station apparatus as defined in claim 1 wherein said base unit includes a plurality of said communication signal generating means and a plurality of said subracks, and wherein said plurality of said communication signal generating means are received in said 20 plurality of said subracks.

25 3. A base station apparatus as defined in claim 2 wherein said plurality of said subracks which have received said plurality of said communication signal generating means are arranged adjacent to each other in said at least one rack.

30 4. A base station apparatus as defined in claim 1 wherein said communication signal generating means is provided on at least one circuit card, and said subrack is configured and adapted to receive said at least one circuit card.

5. A base station as defined in claim 1 wherein said base unit is connected to a communication signal source for supplying the communication signals to said base unit.

5 6. A base station apparatus as defined in claim 5 wherein said base unit is adapted to send the communication signals from said communication signal source to the subscriber equipment at a higher data rate than a data rate of the communication signals received from the subscriber equipment.  
10

15 7. A base station apparatus as defined in claim 6 wherein said base unit converts a data rate of the communication signals received from said communication signal source to a lower data rate, and performs a multiplexing function on the communication signals to send the communication signals at said higher data rate than said data rate of the communication signals received from the subscriber equipment.

20 8. A base station apparatus as defined in claim 7 wherein said base unit includes a multiplexer for converting said data rate of the communication signals received from said communication signal source to said lower data rate.  
25

9. A base station apparatus as defined in claim 7 wherein said multiplexing function is performed by said communication signal generating means.

30 10. A base station apparatus as defined in claim 5 wherein said base unit is connected to said communication signal source via a broad bandwidth connection network.

11. A base station apparatus as defined in claim 1 wherein said communication signal generating means includes video signal generating means and telephony signal generating means, and the communication signals include video signals and telephone signals.

12. A base station apparatus as defined in claim 11 wherein said base unit includes a plurality of said video signal generating means, a plurality of said telephony signal generating means and a plurality of said subracks, and said plurality of said video signal means and said telephony signal generating means are received in said plurality of said subracks.

15

13. A base station apparatus as defined in claim 12 wherein said subracks in which said plurality of said video signal generating means have been received are arranged adjacent to each other in said at least one rack, and said subracks in which said plurality of said telephony signal generating means have been received are arranged adjacent to each other in said at least one rack.

14. A base station apparatus as defined in claim 12 wherein each of said plurality of said video signal means and said telephony signal means is provided on at least one circuit card, and said circuit card is configured and adapted to be received in said plurality of subracks.

30

15. A base station apparatus as defined in claim 11 wherein said telephony signal generating mean generates data signals.

16. A base station apparatus as defined in claim 11  
wherein said base unit is connected to a video signal  
source and a telephony signal source for supplying said  
video signals and said telephony signals, respectively, to  
5 said base unit.

17. A base station apparatus as defined in claim 16  
wherein said base unit is adapted to send said video and  
said telephony signals from said video and said telephony  
10 signal sources to the subscriber equipment at a higher data  
rate than a data rate of said video and said telephony  
signals received from the subscriber equipment.

18. A base station apparatus as defined in claim 17  
15 wherein said base unit converts a data rate of said video  
and said telephony signals received from said video and  
said telephony signal sources to a lower data rate, and  
performs a multiplexing function on said video and said  
telephony signals to send said video and said telephony  
20 signals at said higher data rate than said data rate of  
said video and said telephony signals received from the  
subscriber equipment.

19. A base station apparatus as defined in claim 18  
25 wherein said base unit includes a multiplexer for  
converting said data rate of said video and said telephony  
signals received from said video and said telephony signal  
sources to said lower data rate.

30 20. A base station apparatus as defined in claim 19,  
wherein said multiplexing function is performed by said  
video signal generating means and said telephony signal  
generating means.

21. A base station apparatus as defined in claim 16  
wherein said base unit is connected to said video and said  
telephony signal sources via a broad bandwidth connection  
5 network.

22. A base station apparatus as defined in claim 1  
wherein said communication signal generating means is  
telephony signal generating means and the communication  
10 signals are telephony signals.

23. A base station apparatus as defined in claim 22  
wherein said base unit includes a plurality of said  
telephony signal generating means and a plurality of said  
15 subracks and said plurality of said telephony signal  
generating means are received in said plurality of subracks

24. A base station apparatus as defined in claim 23  
wherein said subracks in which said plurality of said  
20 telephony signal generating means have been received are  
arranged adjacent to each other in said at least one rack.

25. A base station apparatus as defined in claim 23  
wherein each of said plurality of said telephony signal  
25 generating means is provided on at least one circuit card,  
and said circuit card is configured and adapted to be  
received in said plurality of subracks.

26. A base station apparatus as defined in claim 22  
30 wherein said telephony signal generating means generates  
data signals.

20

27. A base station apparatus as defined in claim 22 wherein said base unit is connected to a telephony signal source for supplying said telephone signals to said base unit.

5

28. A base station apparatus as defined in claim 27 wherein said base unit is adapted to send said telephony signals from said telephony signal source to the subscriber equipment at a higher data rate than a data rate of said 10 telephony signals received from the subscriber equipment.

15

29. A base station apparatus as defined in claim 28 wherein said base unit converts a data rate of said telephony signals received from said telephony signal source to a lower data rate and performs a multiplexing function on said telephony signals to send said telephony signals at said higher data rate than said data rate of said telephony signals received from the subscriber equipment.

20

30. A base station apparatus as defined in claim 29 wherein said base unit includes a multiplexer for converting said data rate of said telephony signals received from said telephony signal source to said lower 25 data rate.

31. A base station apparatus as defined in claim 30 wherein said multiplexing function is performed by said telephony signal generating means.

30

32. A base station apparatus as defined in claim 1 wherein said communication signal generating means is a

video signal generating means, and the communication signals are video signals.

5       33. A base station apparatus as defined in claim 32 wherein said base unit includes a plurality of said video signal generating means and a plurality of said subracks, and said plurality of said video signal generating means are received in said plurality of subracks.

10      34. A base station apparatus as defined in claim 33 wherein said subracks in which said plurality of said video signal generating means have been received are arranged adjacent to each other in said at least one rack.

15      35. A base station apparatus as defined in claim 33 wherein each of said plurality of said video signal generating means is provided on at least one circuit card and said circuit card is configured and adapted to be received in said plurality of subracks.

20      36. A base station apparatus as defined in claim 32 wherein said base unit is connected to a video signal source for supplying said video signals to said base unit.

25      37. A base station apparatus as defined in claim 36 wherein said base unit is adapted to send said video signals from said video signal source to the subscriber equipment at a higher data rate than a data rate of said video signals received from the subscriber equipment.

30      38. A base station apparatus as defined in claim 37 wherein said base unit converts a data rate of said video signals received from said video signal source to a lower

data rate, and performs a multiplexing function on said video signals to send said video signals at said higher data rate than said data rate of said video signals received from the subscriber equipment.

5

39. A base station apparatus as defined in claim 38 wherein said base unit includes a multiplexer for converting said data rate of said video signals received from said video signal source to said lower data rate.

10

40. A base station apparatus as defined in claim 39 wherein said multiplexing function is performed by said video signal generating means.

15

41. A base station apparatus as defined in claim 1 wherein said base unit further comprises:

at least one modulator connected between said communication signal generating means and said transmitting/receiving unit for modulating the communication signals; and

at least one demodulator connected between said communication signal generating means and said transmitting/receiving unit for demodulating the communication signals received from the subscriber equipment.

42. A base station apparatus as defined in claim 1 wherein said base unit further comprises a master oscillator for providing a single frequency reference for all frequency setting components of said base station apparatus.

43. A base station apparatus as defined in claim 42 wherein said base unit further comprises a pilot tone generator operationally connected to said master oscillator for providing said frequency reference to said transmitting/receiving unit and the subscriber equipment.

44. A base station apparatus as defined in claim 1 wherein said base unit is connected to said transmitting/receiving unit via one of at least one fiber optic link and at least one coaxial cable.

45. A base station apparatus as defined in claim 44 wherein a frequency of the communication signals transmitted between said base unit and said transmitting/receiving unit is different than a frequency of the communication signals transmitted between said transmitting/receiving unit and the subscriber equipment.

46. A base station apparatus as defined in claim 45 wherein said frequency of the communication signals transmitted between said base unit and said transmitting receiving unit is in intermediate frequency and said frequency of the communication signals transmitted between said transmitting/receiving unit and the subscriber equipment is in radio frequency.

47. A base station apparatus as defined in claim 1 wherein said base station is adapted to receive the communication signals from the subscriber equipment in one of a continuous format and a burst format.

48. A base station apparatus as defined in claim 47 wherein the communication signals in said burst format is

received by said base station in a time-division multiple access (TDMA) scheme.

49. A local multipoint distribution service base station apparatus for sending and receiving communication signals to and from subscriber equipment, comprising:  
5           communication signal generating means for generating the communication signals;  
              a transmitting/receiving unit operationally connected to said communication signal generating means and adapted to transmit/receive the communication signals to and from the subscriber equipment; and  
10          antenna means operatively connected to said transmitting/receiving unit for directing and receiving the communication signals to and from the subscriber equipment;  
              wherein said antenna means and said transmitting/receiving unit are arranged and configured 15 into an integrated assembly.

50. A base station apparatus as defined in claim 49 wherein said antenna means includes a radome/polarizer and an antenna.  
20

51. Local multipoint distribution service base station apparatus for sending and receiving communication signals to and from remotely located subscriber equipment, comprising:

5 a base unit including at least one rack, said rack configured and adapted to receive at least one subrack;

at least one communication signal generating means arranged and configured to be received in said at least one subrack;

10 a transmitting/receiving unit operationally connected to said base unit for transmitting and receiving the communication signals to and from the subscriber equipment; and

15 antenna means operatively connected to said transmitting/receiving unit for directing and receiving the communication signals to and from the subscriber equipment;

wherein said antenna means and said transmitting/receiving unit are arranged and configured into an integrated assembly.

## (54) Title: LOCAL MULTIPONT DISTRIBUTION SERVICE BASE STATION APPARATUS

## (57) Abstract

A local multipoint distribution service base station apparatus for sending and receiving communication signals to and from subscribers includes a base unit having at least one rack which is adapted to receive at least one subrack. At least one communication signal generating unit is also arranged and configured to be received by the subrack. In addition, a transmitting/receiving unit is operationally connected to the base unit for transmitting and/or receiving the communication signals to and from the subscribers.

## INTERNATIONAL SEARCH REPORT

Int'l Application No  
PCT/US 99/25657

A. CLASSIFICATION OF SUBJECT MATTER  
IPC 7 H05K7/18 H04Q7/30 H04Q7/20

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)  
IPC 7 H05K H04Q H04B

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	WO 96 38786 A (DSC COMMUNICATIONS) 5 December 1996 (1996-12-05) page 5, line 25 -page 6, line 6; figure 1	1-48, 51
X	WO 97 29608 A (QUALCOMM INC) 14 August 1997 (1997-08-14)	49, 50
A	page 14, line 22 - line 25; figures 1,3	51
A	US 5 754 961 A (NAKAJIMA NOBUYASU ET AL) 19 May 1998 (1998-05-19) column 9, line 46 -column 11, line 31; figures 3-6	1, 6-21, 28-40

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

## \* Special categories of cited documents :

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family

Date of the actual completion of the international search
